Abstract—Detection based on eigenvalues of received signal covariance matrix is currently one of the most effective solution for spectrum sensing problem in cognitive radios. However, the results of these schemes always depend on asymptotic assumptions since the close-formed expression of exact eigenvalues ratio distribution is exceptionally complex to compute in practice. In this paper, non-asymptotic spectrum sensing approach to approximate the extreme eigenvalues is introduced. In this context, the Gaussian approximation approach based on exact analytical moments of extreme eigenvalues is presented. In this approach, the extreme eigenvalues are considered as dependent Gaussian random variables such that the joint probability density function (PDF) is approximated by bivariate Gaussian distribution function for any number of cooperating secondary users and received samples. In this context, the definition of Copula is cited to analyze the extent of the dependency between the extreme eigenvalues. Later, the decision threshold based on the ratio of dependent Gaussian extreme eigenvalues is derived. The performance analysis of our newly proposed approach is compared with the already published asymptotic Tracy-Widom approximation approach.

Index Terms—Spectrum sensing; eigenvalue ratio based detection; non-asymptotic Gaussian approximation; Copula.

I. INTRODUCTION

In cognitive radio networks, the spectrum resources are available for a secondary user (SU) only when they are not occupied by the primary user (PU), which aims at avoidance of intolerable interference. Thus, the SU should be able to detect the presence of the PU. In this context, high probability of accurate detection in spectrum sensing becomes extremely important in the implementation of cognitive radio networks. Eigenvalue ratio (ER) based detection has been considered as an effective and efficient solution to this problem [1–5]. The key advantage of this detection method lies in the fact that there is no need to obtain a prior information of the PU. The main idea is to decide whether the spectrum resources are being used by a PU or not by exploiting the extreme eigenvalues of the received signal covariance matrix.

Based on the recent results of random matrix theory, the ER detector exploit the ratio between the largest and the smallest eigenvalues of the covariance matrix as analytical statistics

and determine the decision threshold. The decision threshold is precalculated, which is determined by the distribution of the test statistics T_N . However, the exact distribution of the test statistics of the ER detector is generally a mathematically intractable function. Some semi-analytical approaches for the distribution are presented in [5, 6] where the computational complexity becomes intractable with the increase in number of SUs K and received samples N . The exact expression for this ratio has also been derived in [3], however the distribution can only be evaluated numerically. Also, when K and N are large, the complexity of the exact expression may become computationally cumbersome. As a consequence, a Gaussian approximation is introduced in [7] to derive the analytical distribution of T_N such that the decision threshold γ can be calculated in a closed-form. Despite the simplicity of the decision threshold, the proposed approximation is only valid under the assumption that the distribution of the largest and the smallest eigenvalues converges to the Tracy-Widom distribution of order two [8]. It has been also shown that such convergence only occurs when $K \rightarrow \infty$, $N \rightarrow \infty$ and $\frac{K}{N} \rightarrow c \in (0, 1)$. However, the resulting cumulative distribution function (CDF) of the Tracy-Widom random variable involve matrix determinants with function entries that are difficult to evaluate when K and N are larger. The derived decision threshold is based on the asymptotic Gaussianity of the extreme eigenvalue distribution obtained by fitting asymptotic moments of Tracy-Widom distribution of order 2 [8]. Moreover, the approximation is under the assumption that the extreme eigenvalues are independent with each other which leads to inaccuracy of considerable extent for moderate to small number of SUs and samples.

The contributions of this paper are as follows: We introduce a simple non-asymptotic spectrum sensing approach based on non-asymptotic Gaussian approximation for any number of collaborating SUs and received samples. The joint probability density function (PDF) of the largest and the smallest eigenvalues are approximated by a bivariate Gaussian distribution function. The proposed approximation captures the non-asymptotic Gaussianity of the extreme eigenvalues based on their exact analytical moments. The definition of Copula is cited to show that the largest and the smallest eigenvalues

are dependent and their dependency increases with moderate to small values of K and N .

The rest of this paper is organized as follows. Section II defines the system model to explain the detection problem of PU; Section III introduces the Gaussian approximation to the extreme eigenvalues. In this section, we recast the Gaussianity of the extreme eigenvalue distribution in the framework of their exact analytical moments. Dependency analysis based on Gaussian Copula between the extreme eigenvalues is also presented; Finally, we calculate an accurate optimal decision threshold for the false alarm probability. Conclusions are presented in IV.

II. SYSTEM MODEL

Consider there are K collaborating SUs such that each user collects N samples during the sensing time to detect a PU. The SUs may be considered as a K receive antennas in one secondary terminal or K secondary terminals each with single antenna, or any combinations of these. The collected samples from K collaborating SUs will be forwarded to a fusion center for combined processing. The aim of the SU cognitive phase is to construct and analyze tests associated with the following hypothesis testing problem:

$$\mathcal{H}_0 : \mathbf{y}(n) = \mathbf{w}(n) \quad (1)$$

$$\mathcal{H}_1 : \mathbf{y}(n) = \mathbf{h}(n) s(n) + \mathbf{w}(n) \quad (2)$$

where $\mathbf{y}(n) = [y_1(n), \dots, y_K(n)]^T$ is the $K \times 1$ observed complex time series, $\mathbf{w}(n)$ represents a $K \times 1$ complex circular Gaussian white noise process with unknown variance σ_w^2 . In (2), the vector $\mathbf{h}(n) \in \mathbb{C}^{K \times 1}$ typically represents the propagation channel between the PU and K collaborating SUs and the signal $s(n)$ denotes a standard scalar i.i.d circular complex Gaussian process w.r.t samples $n = 1, 2, \dots, N$ and stands for the source signal to be detected. We stack the observed data into $K \times N$ data matrix \mathbf{Y} which may be expressed as

$$\mathbf{Y} = \begin{pmatrix} y_1(1) & y_1(2) & \cdots & y_1(N) \\ y_2(1) & y_2(2) & \cdots & y_2(N) \\ \vdots & \vdots & \ddots & \vdots \\ y_K(1) & y_K(2) & \cdots & y_K(N) \end{pmatrix} \quad (3)$$

The received sampled covariance matrix is $\mathbf{R} = \mathbf{Y}\mathbf{Y}^H$ with ordered eigenvalues $\lambda_1 > \lambda_2 > \dots > \lambda_K > 0$, where $(\cdot)^H$ is the Hermitian conjugate operator. These eigenvalues behave differently depending on the presence or absence of the PU. The spectral properties of the covariance matrix is the reason of using the ratio between the largest and the smallest eigenvalues of this matrix as a test statistics to infer the presence or absence of the PU. The test statistics for ER detector is $T_N = \lambda_1/\lambda_K$ and denoting γ as the decision threshold employed by the detector such that $T_N \underset{\mathcal{H}_0}{\overset{\mathcal{H}_1}{\gtrless}} \gamma$ to decide if the target spectrum resource is occupied or not.

III. NON-ASYMPTOTIC GAUSSIAN APPROXIMATION FOR ER DETECTOR

In this section, we calculate the decision threshold for ER detector based on the Gaussian distribution by exchanging its moments with the exact analytical moments of λ_1 and λ_K .

A. Moments of Largest and Smallest Eigenvalues

Let us denote $\det(\mathbf{A}, \mathbf{B})$ as the cross-determinant of two matrices $\mathbf{A} = \{a_{i,j}\}_{m \times m}$ and $\mathbf{B} = \{b_{i,j}\}_{n \times n}$ with $m \leq n$ such that

$$\det(\mathbf{A}, \mathbf{B}) = \sum_{i=1}^m \sum_{j=1}^m (-1)^{i+j} a_{i,j} B_{i,j} \quad (4)$$

where $B_{i,j}$ is the minor of matrix \mathbf{B} with i -th row and j -th column deleted. The PDF of the largest (λ_1) and the smallest (λ_K) eigenvalues are given by [9]

$$f_{\lambda(\cdot)}(\lambda) = \mathbb{C}_{N,K}^{-1} \det(\mathbf{A}, \mathbf{B}^{(\cdot)}) \quad (5)$$

where the constant $\mathbb{C}_{N,K} = \Gamma_{(K)}(N)\Gamma_{(K)}(K)$ with $\Gamma_{(m)}(n) = \prod_{i=1}^m (n-i)!$; the element of $K \times K$ matrix \mathbf{A} is $a_{i,j} = e^{-\lambda} \lambda^{N-K+i+j-2}$; the elements of $K \times K$ matrix $\mathbf{B}^{(\cdot)}$ for λ_1 and λ_K are $b_{i,j} = \gamma(N-K+i+j-1, \lambda)$ and $b_{i,j} = \Gamma(N-K+i+j-1, \lambda)$ respectively, with $\gamma(\cdot, \cdot)$ and $\Gamma(\cdot, \cdot)$ as the lower and the upper incomplete gamma functions respectively.

Considering the p -th moment of λ_1 and λ_K , we have

$$\mathbb{E} \left\{ \lambda_{(\cdot)}^p \right\} = \mathbb{C}_{N,K}^{-1} \int_0^\infty \det(\mathbf{A}_p, \mathbf{B}^{(\cdot)}) d\lambda \quad (6)$$

$$= \mathbb{C}_{N,K}^{-1} \sum_{i=1}^m \sum_{j=1}^m (-1)^{i+j} \int_0^\infty a_{i,j} B_{i,j} d\lambda, \quad (7)$$

where the element of \mathbf{A}_p are $a_{i,j} = e^{-\lambda} \lambda^{p+N-K+i+j-2}$.

1) *Moments of the Smallest Eigenvalue* (λ_K): For the smallest eigenvalue (λ_K), we have the minors of matrix $\mathbf{B}^{(\cdot)}$ as

$$B_{i,j} = \sum_{\alpha} \text{sgn}(\alpha) \prod_{k=1}^{K-1} \Gamma(N-K+L_{\alpha_k,k}, \lambda), \quad (8)$$

where $L_{\alpha_k,k}$ can be determined by

$$L_{\alpha_k,k} = \begin{cases} k + \alpha_k - 1 & \text{if } \alpha_k < i \text{ and } k < j \\ k + \alpha_k + 1 & \text{if } \alpha_k \geq i \text{ and } k \geq j \\ k + \alpha_k & \text{otherwise} \end{cases} \quad (9)$$

Note that $\Gamma(n, \lambda) = e^{-\lambda} (n-1)! \sum_{l=0}^{n-1} \frac{\lambda^l}{l!}$, then $B_{i,j}$ may be expressed as

$$B_{i,j} = \sum_{\alpha} \text{sgn}(\alpha) e^{-(K-1)\lambda} \prod_{k=1}^{K-1} (N-K+L_{\alpha_k,k}-1)! \times \left(\sum_{l_1 \sim (K-1)}^{L_1 \sim (K-1)} \frac{\lambda^{\sum l_1^{(K-1)}}}{l_1^{(K-1)}!} \right), \quad (10)$$

where

$$\sum_{l_1 \sim n}^{L_1 \sim n} = \sum_{l_1=0}^{(N-K+L_{\alpha_1,1}-1)} \sum_{l_2=0}^{(N-K+L_{\alpha_2,2}-1)} \cdots \sum_{l_n=0}^{(N-K+L_{\alpha_n,n}-1)};$$

$$\mathbb{E}\{\lambda_K^p\} = \mathbb{C}_{N,K}^{-1} \sum_{i,j=1}^K (-1)^{i+j} \sum_{\alpha} \text{sgn}(\alpha) \prod_{k=1}^{K-1} (N - K + L_{\alpha_k,k} - 1)! \left(\sum_{l_1 \sim K-1}^{L_1 \sim K-1} \frac{1}{l_1^{(K-1)!}} \int_0^{\infty} e^{-K\lambda} \lambda^{(\sum l_1^{K-1} + N - K + i + j + p - 2)} d\lambda \right) \quad (11)$$

$$= \mathbb{C}_{N,K}^{-1} \sum_{i,j=1}^K (-1)^{i+j} \sum_{\alpha} \text{sgn}(\alpha) \prod_{k=1}^{K-1} (N - K + L_{\alpha_k,k} - 1)! \left(\sum_{l_1 \sim K-1}^{L_1 \sim K-1} \frac{\Gamma(\sum l_1^{K-1} + N - K + i + j + p - 1)}{l_1^{(K-1)! K \sum l_1^{K-1} + N - K + i + j + p - 1}} \right) \quad (12)$$

$$\mathbb{E}\{\lambda_1^p\} = \mathbb{C}_{N,K}^{-1} \sum_{i,j=1}^K (-1)^{i+j} \sum_{\alpha} \text{sgn}(\alpha) \prod_{k=1}^{K-1} (N - K + L_{\alpha_k,k} - 1)! \left(\sum_{\mathbb{S}} (-1)^{|\mathbb{S}|} \frac{\Gamma(\sum \mathbb{S} + N - K + i + j + p - 1)}{\prod \mathbb{S}! (|\mathbb{S}| + 1)^{\sum \mathbb{S} + N - K + i + j + p - 1}} \right) \quad (16)$$

$\sum l_1^n = (l_1 + l_2 + \dots + l_n)$ and $l_1^n! = l_1! l_2! \dots l_n!$.

By substituting (10) into (7), we have (11) which is showing at top of the page. The p -th moment of the smallest eigenvalue (λ_K) can be calculated using (12).

2) *Moments of the Largest Eigenvalue (λ_1):* Similarly, for the largest eigenvalue (λ_1), we have

$$B_{i,j} = \sum_{\alpha} \text{sgn}(\alpha) \prod_{k=1}^{K-1} \gamma(N - K + L_{\alpha_k,k}, \lambda), \quad (13)$$

where $L_{\alpha_k,k}$ is determined by (9). Note that $\gamma(n, \lambda) = (n-1)! \left(1 - e^{-\lambda} \sum_{l=0}^{n-1} \frac{\lambda^l}{l!}\right)$, we may express $B_{i,j}$ as

$$\begin{aligned} B_{i,j} &= \sum_{\alpha} \text{sgn}(\alpha) \prod_{k=1}^{K-1} (N - K + L_{\alpha_k,k} - 1)! \\ &\times \prod_{k=1}^{K-1} \left(1 - e^{-\lambda} \sum_{l_k=0}^{N-K+L_{\alpha_k,k}-1} \frac{\lambda^{l_k}}{l_k!} \right) \\ &= \sum_{\alpha} \text{sgn}(\alpha) \prod_{k=1}^{K-1} (N - K + L_{\alpha_k,k} - 1)! \\ &\times \left(\sum_{\mathbb{S}} (-e^{-\lambda})^{|\mathbb{S}|} \frac{\lambda^{\sum \mathbb{S}}}{\prod \mathbb{S}!} \right), \end{aligned} \quad (15)$$

where \mathbb{S} is any subset of the set $\{l_1, l_2, \dots, l_{K-1}\}$ with l_k from 0 to $N - K + L_{\alpha_k,k} - 1$, $\sum_{\mathbb{S}}$ is the sum over all the elements in \mathbb{S} , $|\mathbb{S}|$ is the cardinality of subset \mathbb{S} , $\sum \mathbb{S}$ is the sum of all the elements in the subset \mathbb{S} , and $\prod \mathbb{S}!$ is the product of the factoring of each element in \mathbb{S} . For example, if $\mathbb{S} = \{l_{i_1}, l_{i_2}, \dots, l_{i_k}\}$, then we have $|\mathbb{S}| = k$, $\sum \mathbb{S} = l_{i_1} + l_{i_2} + \dots + l_{i_k}$, $\prod \mathbb{S}! = l_{i_1}! l_{i_2}! \dots l_{i_k}!$ and

$$\sum_{\mathbb{S}} = \sum_{l_{i_1}=0}^{(N-K+L_{\alpha_{i_1},i_1}-1)} \sum_{l_{i_2}=0}^{(N-K+L_{\alpha_{i_2},i_2}-1)} \dots \sum_{l_{i_k}=0}^{(N-K+L_{\alpha_{i_k},i_k}-1)};$$

For the special case, when \mathbb{S} is empty, we have $|\mathbb{S}| = 0$, $\sum \mathbb{S} = 0$ and $\prod \mathbb{S}! = 1$. With $B_{i,j}$ above, the p -th moment of the largest eigenvalue (λ_1) can be calculated as given in (16).

Choose $p = 1$ and $p = 2$ to calculate the first and the second moments respectively of λ_K and λ_1 . The numerical values of mean and variance of the extreme eigenvalues are

Fig. 1: CDFs of (a) the largest eigenvalue; (b) the smallest eigenvalue.

shown in Table I. The CDFs of the largest and the smallest eigenvalues for some selected values of K and N are shown in Fig. 1(a) and Fig. 1(b) respectively. The figures illustrate that the proposed non-asymptotic Gaussian approximation based on exact moments of extreme eigenvalues outperforms the approximation based on the moments of the Tracy-Widom distribution. Moreover, our results are in perfect agreement with the empirical results.

B. Joint PDF and Copula of Extreme Eigenvalues

We employ the exact analytical moments of extreme eigenvalues to recast the bivariate Gaussian distribu-

tion function as a joint PDF of extreme eigenvalues. Let $(\lambda_1 \sim \mathcal{N}(\mu_{\lambda_1}, \sigma_{\lambda_1}^2), \lambda_K \sim \mathcal{N}(\mu_{\lambda_K}, \sigma_{\lambda_K}^2))$ be a bivariate Gaussian random variables with

$$\boldsymbol{\mu} = \begin{pmatrix} \mu_{\lambda_1} \\ \mu_{\lambda_K} \end{pmatrix} \text{ and } \boldsymbol{\Sigma} = \begin{pmatrix} \sigma_{\lambda_1}^2 & \rho\sigma_{\lambda_1}\sigma_{\lambda_K} \\ \rho\sigma_{\lambda_1}\sigma_{\lambda_K} & \sigma_{\lambda_K}^2 \end{pmatrix}$$

are the mean and the covariance of bivariate Gaussian distribution function respectively, and where ρ is the correlation coefficient between λ_K and λ_1 . If $f_{\lambda_1, \lambda_K}(x, y)$ is the joint PDF of the extreme eigenvalues then by exchanging the Gaussian moments with the exact analytical moments of extreme eigenvalues, the joint PDF can be approximated as

$$f_{\lambda_1, \lambda_K}(x, y) = \frac{1}{2\pi\sigma_{\lambda_1}\sigma_{\lambda_K}(1-\rho^2)^{0.5}} \exp\left(-\frac{z}{2(1-\rho^2)}\right) \quad (17)$$

where

$$z \equiv \frac{(x - \mu_{\lambda_1})^2}{\sigma_{\lambda_1}^2} - \frac{2\rho(x - \mu_{\lambda_1})(y - \mu_{\lambda_K})}{\sigma_{\lambda_1}\sigma_{\lambda_K}} + \frac{(y - \mu_{\lambda_K})^2}{\sigma_{\lambda_K}^2}$$

Now, we analyze the dependency between the random variables (λ_1, λ_K) to approximate ρ by plotting their Copula. A Copula is a multivariate distribution function with known marginal cumulative distribution functions (CDFs) [10]. More specifically, a bivariate joint distribution function $F_{\lambda_1, \lambda_K}(x, y) = Pr\{\lambda_1 \leq x, \lambda_K \leq y\}$ of two random variables λ_1 and λ_K , may be represented by a Copula C as a function of their marginal CDFs $F_{\lambda_1}(x) = Pr\{\lambda_1 \leq x\}$ and $F_{\lambda_K}(y) = Pr\{\lambda_K \leq y\}$ and therefore may be expressed as [10]

$$F_{\lambda_1, \lambda_K}(x, y) = C(F_{\lambda_1}(x), F_{\lambda_K}(y)) \triangleq C(u, v) \quad (18)$$

where $u = F_{\lambda_1}(x)$ and $v = F_{\lambda_K}(y)$; $C(u, v)$ is the associated Copula distribution function. Thus, we have

$$C(u, v) = F_{\lambda_1, \lambda_K}(F_{\lambda_1}^{-1}(u), F_{\lambda_K}^{-1}(v)) \quad (19)$$

By exploiting the chain rule, the corresponding joint PDF $f_{\lambda_1, \lambda_K}(x, y)$ may be decomposed as

$$\begin{aligned} f_{\lambda_1, \lambda_K}(x, y) &= \frac{\partial^2 F_{\lambda_1, \lambda_K}(x, y)}{\partial x \partial y} = \frac{\partial^2 C(F_{\lambda_1}(x), F_{\lambda_K}(y))}{\partial x \partial y} \\ &= \frac{\partial^2 C(u, v)}{\partial u \partial v} \frac{\partial F_{\lambda_1}(x)}{\partial x} \frac{\partial F_{\lambda_K}(y)}{\partial y} \triangleq c(u, v) f_{\lambda_1}(x) f_{\lambda_K}(y) \quad (20) \end{aligned}$$

It is obvious that the joint PDF is the product of the marginal PDFs $f_{\lambda_1}(x)$ and $f_{\lambda_K}(y)$ and Copula density function $c(u, v)$. The definition of Copula identifies a strong relationship which provides link between the marginal PDFs/CDFs and the respective joint PDF/CDF. Also, $c(u, v) = 1$, for independent random variables [10].

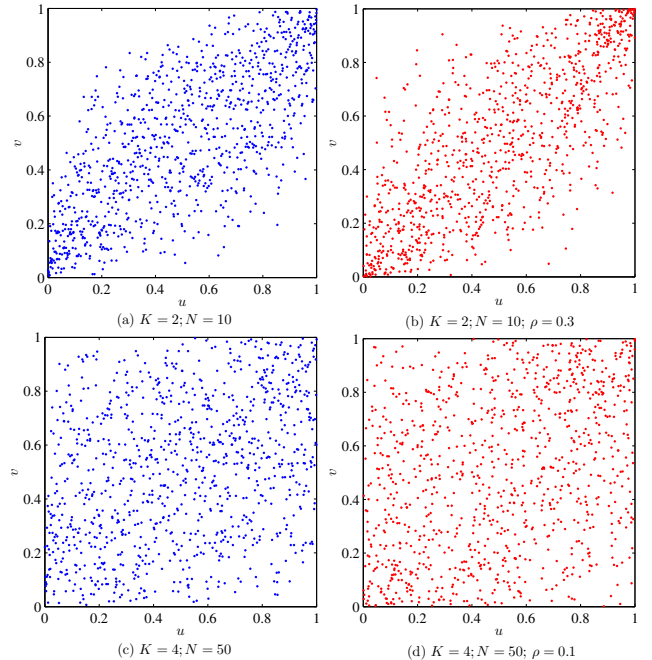

Fig. 2: Plots of Copula between random variables λ_1 and λ_K based on empirical (blue scatter plot) and Gaussian (red scatter plot) marginal distribution functions.

Let $\Phi_{\lambda_1}(x)$ and $\Phi_{\lambda_K}(y)$ are the marginal distribution functions of the approximated Gaussian random variables λ_1 and λ_K respectively. Using the statistical values of $\mu_{\lambda_1}, \mu_{\lambda_K}, \sigma_{\lambda_1}^2, \sigma_{\lambda_K}^2$, the Copula distribution of (17) is given by [10]

$$C(u, v) = \int_{-\infty}^{\Phi_{\lambda_1}^{-1}(u)} \int_{-\infty}^{\Phi_{\lambda_K}^{-1}(v)} f_{\lambda_1, \lambda_K}(x, y) dx dy \quad (21)$$

where $\Phi_{(\cdot)}^{-1}(\cdot)$ is the inverse of the standard univariate Gaussian distribution function.

The plots of Copula between λ_1 and λ_K based on the empirical and Gaussian marginal distribution functions are showing in Fig. 2(a) and Fig. 2(b) respectively for $(K, N) = (2, 10)$. It can be seen that the structure of Copula based on the empirical distribution functions appears same as the Copula structure based on the Gaussian distribution functions for $\rho = 0.3$. Similar kind of observation can be made from Fig. 2(c) and Fig. 2(d) when $(K, N) = (4, 50)$ and correlation reduces to $\rho = 0.1$. It can also be noticed that the Copula structure is distinctive for small value of K and N , i.e. the extreme eigenvalues are dependent. However, with the increase in number of K and N , the dependency between λ_1 and λ_K decreases. The

$$\gamma = \frac{\mu_{\lambda_1}\mu_{\lambda_K} - \tau^2\rho\sigma_{\lambda_1}\sigma_{\lambda_K}}{\mu_{\lambda_K}^2 - \tau^2\sigma_{\lambda_K}^2} + \frac{\tau\sqrt{\mu_{\lambda_1}^2\sigma_{\lambda_K}^2 + \mu_{\lambda_K}^2\sigma_{\lambda_1}^2 + (\rho^2 - 1)\tau^2\sigma_{\lambda_1}^2\sigma_{\lambda_K}^2 - 2\mu_{\lambda_1}\mu_{\lambda_K}\rho\sigma_{\lambda_1}\sigma_{\lambda_K}}}{\mu_{\lambda_K}^2 - \tau^2\sigma_{\lambda_K}^2} \quad (24)$$

same is shown in Fig. 2. Therefore, the dependency between λ_1 and λ_K can not be ignored if accurate spectrum sensing is required. However, some analytical approaches may be applied to calculate the exact value of ρ .

C. Calculation of Decision Threshold

We have already shown that the joint PDF of (λ_1, λ_K) can be well approximated by a bivariate Gaussian distribution function knowing their exact moments and ρ . If the joint PDF of $(\lambda_1, \lambda_K) \sim \mathcal{N}(\boldsymbol{\mu}, \boldsymbol{\Sigma})$ is given as (17), then the CDF of the ratio of two dependent Gaussian random variables may be expressed as [11]

$$F(\gamma) = \Phi \left\{ \frac{\mu_{\lambda_K}\gamma - \mu_{\lambda_1}}{\sigma_{\lambda_1}\sigma_{\lambda_K}a(\gamma)} \right\} \quad (22)$$

where $a(\gamma) = \left(\frac{\gamma^2}{\sigma_{\lambda_1}^2} - \frac{2\rho\gamma}{\sigma_{\lambda_1}\sigma_{\lambda_K}} + \frac{1}{\sigma_{\lambda_K}^2} \right)^{0.5}$ and $\Phi(\cdot)$ is the CDF of a standard Gaussian random variable. Using (22), we may calculate an accurate decision threshold analytically in closed form based on exact moments. For a given target false alarm probability (P_{fa}) and fixed ρ , the decision threshold γ is obtained by solving

$$P_{fa} = 1 - F(\gamma) \quad (23)$$

The solution is shown at the top of the page as (24), where $\tau = \Phi^{-1}(1 - P_{fa})$.

In Fig. 3, we plot the decision threshold γ as a function of P_{fa} for small and moderate number of K and N to compare the Gaussianity of λ_1 and λ_K based on exact moments with their Gaussianity based on the moments of Tracy-Widom distribution. It can be seen that the proposed non-asymptotic Gaussian approximation performs extremely well in comparison with the Tracy-Widom approximation approach and our results match the empirical results. The proposed approximation is equivalently good for any number of K and N , however the results are significantly accurate for reasonably moderate to small number of K and N .

IV. CONCLUSION

In this paper, a non-asymptotic Gaussian approximation based on the exact analytical moments of the extreme eigenvalues has been employed to approximate the decision threshold of ER detector. Copula plots show that the extreme eigenvalues are dependent and their dependency should not be ignored specially for moderate to small number of N and K . The accuracy of decision threshold based on Gaussian approximation has been evaluated in comparison with decision threshold calculated using Tracy-Widom approximation approach. It has been shown that our proposed approach is accurate enough for any number of N and K .
